INTRODUCTION

We shape our buildings; thereafter they shape us.¹

— Winston Churchill

On March 28, 2000, one hundred commercial office buildings throughout the United States received an Energy Star Label, “the federal government’s highest symbol of excellence for energy efficiency and environmental conservation.”² To qualify for Star status, which certifies buildings in the top quarter of comparable buildings in terms of energy efficiency, a building must meet certain energy performance criteria; it must also satisfy minimum standards for healthy indoor air quality.³ The Environmental Protection Agency (EPA) and the United States Department of Energy (USDOE) created the designation in 1998 “as an incentive for the [real estate] industry to reduce demand for electrical energy use and, thereby, help lower greenhouse gas emissions.”⁴

Four Times Square, a forty-eight story post modern office tower in the heart of Manhattan’s Times Square, was one of the recipients of an Energy Star Label.⁵ The Durst Organization, its developer, chose a site that at the time seemed highly incongruous to the stringent, globally conscious, environmental construction standards it required of the entire project team.⁶ Completed in 1998, the building was America’s first environment-friendly, large-scale green construction project, and it quickly became an important focal point of the

¹ Winston Churchill, 393 Parl. Deb., H.C. (5th ser.) (1943) 403.
² See Real Estate Roundtable Members Receive Government’s First Energy Star Building Award, PR NEWSWIRE, Mar. 28, 2000 (on file with Audra S. Capas of Real Estate Roundtable at acapas@rer.org) [hereinafter Real Estate Roundtable]. Energy Star is a government-backed program that seeks to protect the environment by promoting superior energy efficiency. In 2003, Energy Star saved Americans enough energy to power 20 million homes, greenhouse emission from 18 million cars and over 9 billion dollars. What is Energy Star?, Energy Star Website, at http://www.energystar.gov/index.cfm?c=about.abindex (last visited Nov. 1, 2004) [hereinafter What is Energy Star?].

⁵ See What is Energy Star?, supra note 2 ("For us and our tenants, high-performance buildings make both economic and ecological sense.") (statement of Douglas Durst, President of The Durst Organization).
ongoing controversy over the purported benefits of sustainable design.\textsuperscript{7} Notably, the tower's success as America's first green high-rise indirectly led to the creation of the United States Green Building Council's (USGBC) Leadership in Energy and Environmental Design (LEED) Green Building Rating System for high performance buildings.\textsuperscript{8} The critical acclaim that the building's innovative sustainable design concepts received, in both architectural and academic circles, encouraged developers across the street at Three Times Square to adopt similar green standards for their new high-rise office building.\textsuperscript{9} Boston Properties, the developer of the final two office towers in the Times Square redevelopment scheme, chose not to incorporate green elements into either of its structures despite the acclaim Four Times Square had received.\textsuperscript{10}

The overwhelming lack of uniform green design elements in America's most important modern high-rise buildings, in spite of substantial guidance for developers and contractors provided through programs like LEED,\textsuperscript{11} has led some to suggest that the purported economic and environmental benefits of such construction are illusory. This suggestion is erroneous. The necessity for green design in responsible twenty-first century architecture becomes frighteningly clear upon an examination of the impact high-rise construction has on the natural environment; the construction, maintenance, and operation of residential and commercial buildings in the United States produces numerous negative externalities which wreak havoc on the natural ecosystems in which those structures are erected.\textsuperscript{12} Moreover, many universally accepted global

\textsuperscript{7} A green, sustainable, or high performance building is "a building that minimizes impact on the environment through conservation of resources (energy, water, etc.) and contributes to the health of its occupants. Green buildings are characterized by comfortable and aesthetically pleasing environments." \textsc{David Gissen, Big & Green: Toward Sustainable Architecture in the 21st Century} 184 (2002).

\textsuperscript{8} See John Holusha, \textit{New Technology Enhances Marketing and Design}, \textsc{N.Y. Times}, June 7, 1998, at RE7 (stating that "new technology is changing the way office buildings are designed and the way they are offered to customers.").

\textsuperscript{9} See \textsc{Gissen, supra} note 7, at 24 (stating that Three Times Square is "one of the two largest environmentally sensitive buildings in the United States, along with [Four Times Square]."); see also John Holusha, \textit{A Corporate Headquarters Next to Bugs and Mickey}, \textsc{N.Y. Times}, Sept. 6, 1998, at RE 9 (providing a broad overview of green design elements featured at Three Times Square).

\textsuperscript{10} See Boston Properties, \textsc{at http://www.bostonproperties.com} (last visited Nov. 1, 2004), for a description of the developer's Five Times Square and Times Square Tower projects.

\textsuperscript{11} See discussion \textsc{infra} Part II.B, for a detailed explanation, examination, and discussion of USGBC's LEED rating system.

\textsuperscript{12} Charles J. Kibert, \textit{Listen to Your Mother: Environment Friendly Construction Techniques}, \textsc{Alternatives Journal}, Jan. 1, 2000, at 38 [hereinafter Kibert, \textit{Listen to Your Mother}]; see also Charles J. Kibert, \textit{Policy Instruments for a Sustainable Built Environment}, 17 \textit{J. Land Use & Envtl. L.} 379, 384 (2002) [hereinafter Kibert, \textit{Policy Instruments}] (stating that "[i]n the U.S., the construction industry clearly has disproportionate impacts on the environment compared to other sectors of the economy. . . . Although it represents just 8% of the U.S. GDP, [it] is responsible for over 40% of total materials extracted to produce and alter buildings and infrastructure . . . ").
environmental problems have been directly or indirectly associated with the built environment. Buildings occupy significant amounts of land, modify natural hydrologic cycles, contribute to global climate change, affect biodiversity, contribute to soil erosion, have major impacts on water and air quality, and are sources of major quantities of solid waste. It follows that promoting green buildings is essential to the ecological future of both our country and our planet.

The green building movement promotes design and construction practices that significantly reduce or eliminate a building’s negative impact on its occupants and surrounding natural environment. The movement attempts to accomplish this through sustainable site planning, use of energy efficient systems and renewable energy sources to power building systems, conservation of materials and natural resources used during construction, and creation of higher levels of indoor environmental quality. USGBC’s LEED Green Building Rating System, created in 1998, is a “voluntary, consensus-based national standard for developing high-performance, sustainable buildings. Members of the USGBC[,] representing all segments of the building industry[,] developed LEED and continue to contribute to its evolution.” LEED was created to bring uniformity to the American green building movement by establishing a common standard of measurement for green building elements, promoting integrated, whole-building design practices, recognizing environmental leadership in the building industry, stimulating green competition, raising consumer awareness of green building benefits, and transforming the building market. Developers seeking
LEED certification for their buildings earn points by “meeting or exceeding each credit’s technical requirements.” The LEED guidelines, available for free at USGBC’s website for project teams, provide a brief description of technologies and strategies for each credit to inform developers and contractors who might be unfamiliar with that particular credit category. They do not, however, provide developers with financial incentives for incorporating green elements into their projects or refer to any of the numerous state and local green building programs currently in existence. Resolving this shortcoming in LEED remains USGBC’s greatest challenge for the future.

One developer on the cusp of the green building movement is The Hines Company, one of the World’s largest private developers, investors, and managers of commercial real estate. It has engaged such prominent architects as Philip Johnson, Cesar Pelli, I.M. Pei, and Frank Gehry to design its signature projects and currently manages over eighty million square feet of office space in thirteen different countries, valued at $14 billion. Acknowledging its massive global presence and the corresponding impact of its buildings on the natural environment, Hines has championed green design in the commercial buildings it has developed in Boston, Seattle, Houston, Detroit, and Atlanta. Other well-known developers, such as The Durst Organization, have also invested heavily in high performance buildings despite the premium costs they implicate. The extra forty-five cents to $1.30 per square foot over standard construction costs that green design requires is justified, they hope, through the realization of other types of savings throughout the building’s lifespan.

To date, however, real estate industry experts are sharply divided over whether those savings will ever materialize; some have even stated that claims of beneficial returns remain unsubstantiated or have been greatly exaggerated. According to Hines partner Kenneth W. Hubbard, green design has failed to...
catch on with developers at large, particularly in commercial buildings. He maintains that in order for green design to become popular among developers, proponents must present substantial empirical evidence of its economic benefits to owners. Edward W. Caulkins, a senior director of global property manager Cushman & Wakefield and a sitting member of USGBC, has publicly drawn attention to the prohibitively high cost of green design for developers. He once derisively noted that, “at the end of the day, you [as a developer] get a [LEED certification] plaque.” Building Design & Construction magazine has said that “[m]any speculative office developers consider sustainable design an expensive and troublesome luxury that offers little return on their investment dollar.”

The magazine’s November, 2003 White Paper on Sustainability suggested that it is not possible to sell sustainable design at Class A rates based on energy savings alone. Other developers have echoed those sentiments, arguing that “[t]he biggest benefit in environmentally sensitive design is the probability that you [are] going to get increased productivity from the people who work there.... You [are not] going to sell [sustainable design] on energy savings alone.” Still others such as Robert C. Larson, chairman of Lazard Freres Real Estate Investors, have called some of the methods introduced by USDOE and EPA to measure a building’s application of energy-efficient systems “helpful to investors in valuing and differentiating real estate portfolios and asset

---

27 Id. As of Aug. 11, 2003, however, eighteen percent of all LEED registered projects were commercial buildings, second only to multi-use structures at twenty percent. UCGBC INTRODUCTION, supra note 16.

28 Brick, supra note 24, at C5.

29 “[T]he Green Building Council’s certifications, created as a marketing tool for developers and building owners, have even in their infancy become less than compelling to their intended audience, corporate tenants, according to [real estate] brokers and developers across the country.” Brick, supra note 24, at C5.

30 Larry Flynn, Where Passion Prevails, BUILDING DESIGN & CONSTRUCTION, Nov. 2003, at 32.

31 Class A office space is that found in the most "prestigious buildings, competing for premier office users with above-average rental rates for the area along with high-quality standard finishes, state of the art systems, exceptional accessibility and a definite market presence." Glossary of Real Estate Terms, OfficeFinder: Information and Referral Network, at http://www.officefinder.com/glossary.html (last visited Mar. 17 2004).

32 BUILDING DESIGN & CONSTRUCTION, WHITE PAPER ON SUSTAINABILITY 33 (Nov. 2003), available at http://www.bdcmag.com/newstrends/BDCWhitePaperR2.pdf (last visited Nov. 19, 2004) [hereinafter WHITE PAPER]. “Whether the rental market will pay a premium for sustainable design is another issue . . . except in cases where tenants pay their own utilities. Then . . . it may be possible to charge a rental premium on the basis of lower utility bills, but this is rare.” Id.

33 See Flynn, supra note 30, at 32 (statement of Hugh J. Zimmer, CEO of the Zimmer Companies, a Kansas City-based commercial real estate developer which in 2002 completed a 130,000 square foot office complex in Lenexa, Kansas that earned the state its first ever LEED certification). See also discussion infra Part III A-B, where the purported financial benefits of green design, including those from energy savings are examined in detail.
management strategies.\textsuperscript{34} Clearly, the real estate community is not united in its appraisal of green design.

California’s Sustainable Building Task Force’s October, 2003, report was the first comprehensive empirical study on the costs and financial benefits of green buildings.\textsuperscript{35} The report decisively concluded that green building is indeed cost-effective.\textsuperscript{36} So who is the developer to believe, and why? Is following the LEED guidelines an exercise in futility for developers, or will it result in substantial financial and environmental benefits? This article will answer these questions by first arguing that green design is essential to the long-term viability of large-scale, twenty-first century construction projects in both the commercial and residential sectors of the industry. Part I of the article demonstrates that the green building movement has the potential to provide enormous unrecognized economic, environmental, and health benefits. Many of these benefits have not yet been analyzed or even contemplated by LEED. For the movement to succeed, the government and USGBC must do more to create awareness of green design and encourage its further use in heavy construction projects.

Part II of this article discusses the massive environmental impact of buildings and argues that sustainable design standards are imperative for responsible twenty-first century architecture. Part III examines the purported benefits, both financial and environmental, of green design and concludes that such benefits do exist, though LEED does not sufficiently emphasize those of greatest importance to developers. In Part IV, the current LEED rating system is analyzed through a case study of the green design features at Four Times Square, and recommendations are made about how USGBC can better encourage green design through revising LEED. Part V advances broader social and policy arguments in support of green design, which USGBC should consider incorporating into future versions of LEED.

\textsuperscript{34} See Real Estate Roundtable, supra note 2. Richard Ziman, chairman and CEO of Arden Realty, the 2000 winner of EPA’s Commercial Real Estate Owner of the Year award for owning the most energy efficient buildings in the United States, said “[w]e worked hard to achieve the top position nationally in the Energy Star program because we recognize that meeting the EPA’s benchmark not only benefits the environment, it creates value for our shareholders.” \textit{Id.}

\textsuperscript{36} \textit{Id.} at ix. “Despite data limitations and the need for additional research in various areas, the findings of this report point to a clear conclusion: building green is cost-effective and makes financial sense today.” \textit{Id.}
I. SUSTAINABLE DESIGN STANDARDS: A 21ST CENTURY NECESSITY

A. The Environmental Impact of Buildings

Before examining the benefits of green design, it is first necessary to appreciate the massive local and global impact buildings have on natural environments, which green building programs like LEED were designed to ameliorate. To operate a building, coal, oil, natural gas, and uranium must be extracted, processed, and then transported via train, truck, barge, or ship to power plants for conversion into electricity. Further, transmission lines must be constructed to distribute the electricity.\(^{37}\) Forty percent of the raw materials extracted in the United States each year are used in the construction of residential and commercial buildings, industrial infrastructure, or otherwise incorporated into the built environment, including natural resources such as wood and cork, and minerals such as iron and aggregates.\(^{38}\) Beyond that, it has been estimated that over ninety percent of the materials ever extracted in the United States still exist today as part of its built environment.\(^{39}\)

Importantly in the post-9/11 world, the built environment consumes vast amounts of energy. In the United States, buildings are responsible for approximately sixty-two percent of electricity consumption, over thirty-six percent of total primary energy use, as well as thirty percent of greenhouse gas emissions.\(^{40}\) Measured in dollars, the energy required to power buildings in the United States costs owners over $228 billion every year, a quarter of which is wasted by building systems that are designed or operated poorly.\(^{41}\)

Buildings also contribute to the United States' waste problem. The United States produces 145 million metric tons (MMT) of construction and demolition waste every year, compared with 280 MMT of municipal solid waste, meaning that approximately one third of the total waste sent to landfills each year is a

\(^{37}\) Kibert, Policy Instruments, supra note 12, at 379; see GISSEN, supra note 7, at 115 (2002).

An architect's choice of materials in Manhattan, for example, triggers a series of events halfway around the globe in Madagascar or Brazil. Depending on the material- it might be raw gravel for cheap concrete, a rare, precious cabinet wood, or iron ore for steel beams - an architect's uninformed choices might contribute in some small way to deforestation, an increase in toxic mine tailings, or the loss of biological and cultural diversity. A preponderance of uninformed choices has led to the slow unraveling of the web of life. Id. (emphasis removed).

\(^{39}\) Kibert, Policy Instruments, supra note 12, at 379.

\(^{40}\) USGBC INTRODUCTION, supra note 16, at 5.

direct byproduct of building construction.\textsuperscript{42} Buildings contribute 136 million tons of construction and demolition waste each year, or approximately 2.8 pounds per person in the United States per day, and consume twelve percent of the nation’s potable water supply.\textsuperscript{43} Commercial buildings can consume millions of gallons of water daily and shed the same amount during a storm as runoff, which can absorb toxic construction materials before entering sewers or the site’s groundwater.\textsuperscript{44}

The United States has only five percent of the world’s population, but accounts for nearly twenty-five percent of annual global energy use.\textsuperscript{45} American buildings have a huge global energy and environmental impact, which is largely un-remarked upon in comparison to that of automobiles, power plants, and factories. USGBC and LEED were purportedly designed to help minimize this staggering impact.\textsuperscript{46}

Perhaps most importantly, however, are the subtle yet striking impacts that buildings have on their tenants’ environmental awareness. Modern buildings inherently divorce their occupants from nature, providing them with an insulated space in which to conduct their business and lives. In numerous ways, these spaces prevent tenants, many of whom spend most of their waking lives within the artificial confines of the building’s systems,\textsuperscript{47} from appreciating the fact that they belong to the much larger, natural global ecosystem; consequently, tenants often believe that their personal health is independent from the health of our planet as a whole.\textsuperscript{48} Moreover, recent studies argue that most types of cancer are caused by environmental factors;\textsuperscript{49} given how much time people spend

\end{footnotesize}
performing their jobs inside structures it is hardly surprising that many are calling for the construction of healthier buildings.\footnote{See generally Ross A. Leventhal, "Greening a Profession, \textit{Architecture Week}, Aug. 23, 2000, at C2 1; see also Alex Tynberg, \textit{The Natural Step and Its Implication for a Sustainable Future}, \textit{Hastings W.-Nw. J. Envtl. L. \\& Pol'y} 73 (2000) ("The current economic and legal system in the United States fails to guide society towards a sustainable future . . . . The key to achieving sustainability is to change the practices of commerce, which presently exist unencumbered by real connections to the environment.").} Part V of this article continues to develop these arguments and calls upon USGBC to further include them in later versions of LEED.

\subsection*{B. Historical Overview of Green Building in the United States}

The first use of the term "green" in American architectural circles can be traced to \textit{Architecture} magazine in the mid-1990s.\footnote{Nathan Engstrom, \textit{The Rise of Environmental Awareness in American Architecture: From the Bruntland Commission to LEED}, in KATS, supra note 35, at 2 n.19.} It seems likely, from the numerous programs already in place and the growing list of LEED certified projects, that the nascent green building movement is poised to flourish as a legitimate arm of the architecture discipline.\footnote{See KATS, supra note 35, at 2 ("It is therefore unimpressive that there is already an emerging national consensus on the definition of a green building and a rapidly increasing number of green projects in both the public and private sectors.").} Although USGBC, and its attempt to create a comprehensive, uniform standard for sustainable design through LEED, has existed for only a short period of time, architects and engineers have struggled for over a century to minimize the profound effects that structures have on their surrounding natural environment.\footnote{See generally FRAMPTON, supra note 13, at 178-85.} For example, Milan’s famous Galleria Vittorio Emanuele II, built in the late nineteenth century, used passive systems such as roof ventilators and underground air-cooling chambers to moderate indoor temperatures.\footnote{WHITE PAPER, supra note 32, at 4.} The early 20th century Flatiron Building and New York Times Building in Manhattan used deep-set windows\footnote{Deep-set windows are generally placed shallower in the building’s wall with greater sill area, thus shielding the interior from penetrating light. FRAMPTON, supra note 13, at 55.} to shade workers from the effects of the sun.\footnote{See WHITE PAPER, supra note 32, at 4.}

Prior to World War II, the United States had little need for the modern skyscraper, as compared to today, for a variety of reasons. Blue-collar workers accounted for almost ninety percent of America’s workforce at that time and widespread demand for large amounts of office space across all sectors of the economy was not very strong.\footnote{See Georgette C. Poindexter, \textit{Light, Air, or Manhattanization?: Communal Aesthetics in Zoning Central Real Estate Development}, 78 B.U. L. Rev. 445, 452 (1998).} By the end of the century, however, forty
percent of the workforce was employed in the office sector.\textsuperscript{58} This fundamental
shift in the American economy from manufacturing to services increased
demand for highly concentrated office spaces and consequently led to the
construction of high-rise buildings in new urban commercial and residential
centers.\textsuperscript{59} After World War II, in particular, many of those new urban centers
were designed in a "profoundly anti-urban way; instead of building whole
places, the new system produced an endless series of isolated fragments which pull[ed] apart and isolate[d] the city.... Mixed-use, mixed income neighborhoods
turned into single-use, single-income enclaves connected by roads for vehicles, not pedestrians.\textsuperscript{60}

As building technologies improved, the urban landscape changed
dramatically. Architects like Mies Van der Rohe, Le Corbusier, and other
champions of the International Style\textsuperscript{61} used new air-conditioning, fluorescent
lighting, structural steel, and reflective glass technologies to introduce the "glass
box" skyscraper into architectural studios as the \textit{de facto} structure of choice for
both commercial and residential projects.\textsuperscript{62} Jane Jacobs' famous 1961 book, \textit{The
Death and Life of Great American Cities}, was read widely in both academic and
professional circles and spawned the birth of the New Urbanism movement,
which tried to move the discipline away from the austerity and artificiality of the
International Style.\textsuperscript{63} Similarly, in the 1970s and 1980s, influential thinkers

dense brick, but the open box." \textit{Id.}
\textsuperscript{62} See \textit{id.} at 248-62, for a broad overview of the International Style architectural movement
during the period 1925-1965.
\textsuperscript{63} The New Urbanism movement:

\textit{[V]iews the divestment in central cities; the spread of placeless sprawl; increasing
separation by race and income; environmental deterioration; loss of agricultural lands and
wilderness; and the erosion of society's built heritage as one interrelated community-
buidling challenge. It stands for...the reconfiguration of sprawling suburbs into
communities of real neighborhoods and diverse districts...[s]treets and squares...encourag[ing] and enable[ing] neighbors to know each other and protect their
communities.}

Gindroz, \textit{supra} note 60, at 1427; \textit{see also} JACOBS, \textit{supra} note 60, at 3 ("[T]his book is an attack on
encouraged architects and engineers to begin experimenting with different materials and building systems, which ultimately led to the June, 1993 World Congress of Architects in Chicago. Six thousand architects signed the Declaration of Interdependence for a Sustainable Future, and the conference is now "recognized as a turning point in the history of the green building movement." Over the next seven years, President Clinton signed executive orders relating to sustainability and became a vocal proponent of the newly created USGBC and its LEED sustainability rating system.

USGBC was established in 1993 to promote green design in new construction projects by emphasizing the benefits green design confers on owners. Such benefits may include: higher building system performance at lower cost through synergies between disparate technologies due to integrated designs; lower overall operating costs due to lower utility costs; decreased vacancy rates through improved retention of tenants, leading to substantial marketing advantages for developers looking to obtain leases from other potential tenants; reduced liability and insurance premiums because of an improved risk management strategy; higher levels of overall employee satisfaction because of a healthier workplace; greater volumes of retail sales (studies have shown a forty percent improvement in retail spaces with more natural light); and an increased overall valuation of the building.

USGBC's green building pilot program, LEED 1.0, was unveiled in late-1998, a year in which over one million square feet of building space was registered. Problems with the pilot program were quickly exposed. For example, credits were "either too prescriptive or already standard practice" in the industry, while energy-related credits were not "sufficiently related to performance." The result of this criticism was the creation of LEED 2.0 in 2000, with further refinements in 2003 under LEED 2.1. As of September,
2003, 948 projects totaling 148 million square feet of space have been registered with the program. Unfortunately, many of the same problems exist under this latest update. Further, numerous pre-existing state and local programs provide developers with financial incentives for going green. LEED's failure to provide similar incentives remains its most glaring weakness.

II. PRE-LEED GREEN BUILDING PROGRAMS AT THE STATE AND LOCAL LEVEL

The first local green building program in the United States was established in Austin, Texas in 1991. Today, over two-dozen similar programs exist across the United States. Cities such as Portland, Seattle, and Pittsburgh give grants to developers exploring energy modeling, commissioning, and other related cost options in their buildings. Some cities offer expedited permit review processes and preferred zoning considerations for buildings with sufficient levels of sustainable features. Santa Barbara, California, Scottsdale, Arizona, and Arlington County, Virginia are among the jurisdictions pioneering these types of incentive programs. The Santa Barbara Innovative Building Design Review Committee was the first, and provides "fast track" permit approvals for projects with "superior environmental performance," which are awarded by a voluntary panel of local environmental construction specialists. As part of its Green Points Building Program, Boulder, Colorado became the first municipality in the country to require green design elements in all new residential construction and remodeling projects greater than 500 square feet. In 2001, Frisco, Texas enacted the first green building city ordinance in the United States, incorporating

EPA’s Energy Star program.\textsuperscript{81}

Several states, including New York, Maryland, Massachusetts, and Oregon now provide developers with tax credits for constructing LEED-certified buildings.\textsuperscript{82} New York’s credit was the first of its kind in the United States and was passed as part of the state budget in 2000.\textsuperscript{83} It became effective on January 1, 2001 and the state’s Department of Environmental Conservation began accepting credit applications from developers on September 30, 2002.\textsuperscript{84}

Local governments have also sought to advance green building by addressing the solid waste problem that buildings create. Massachusetts, for example, will soon become the first state to ban the disposal of demolition and construction waste in landfills.\textsuperscript{85} General contractors who have already volunteered to participate in the program separate prohibited materials, which include asphalt, concrete, wood, gypsum wall board (drywall), and various metals, from other non-recyclable materials at the project site to avoid commingling in dumpsters.\textsuperscript{86} Massachusetts officials anticipate that other Northeastern states will adopt similar programs once it becomes apparent that such bans do not create any additional costs for general contractors.\textsuperscript{87}

One of the persistent problems plaguing these existing green building programs, including LEED, is establishing a concrete, precise, and uniform definition of what it means to build green across the variety of different construction disciplines.\textsuperscript{88} Although the solution to this overarching problem is beyond the scope of this article, there are obvious ways in which both LEED, America’s most important green building program, and local programs can be improved, particularly with regard to high-rise construction. Part III of this Article examines the benefits that green design purportedly confers on developers and makes recommendations on which benefits LEED should place

greater emphasis when encouraging developers to incorporate green elements into their buildings.

III. THE DEBATE OVER GREEN BUILDING: ARE PURPORTED BENEFITS FACT OR FICTION?

A. Does Green Cost More to Build?

The starting point for an analysis of LEED is an examination of the purported financial benefits of green design. There are few comprehensive empirical studies analyzing the costs and returns from incorporating green elements into a building’s design to earn LEED credits. The first, an October, 2003 study prepared for the California Sustainable Task Force, entitled The Costs and Financial Benefits of Green Buildings, found that:

[T]he average premium for... green buildings is slightly less than 2% ($3-5 per square foot), substantially lower than is commonly perceived. The majority of this cost is due to the increased architectural and engineering design time necessary to integrate sustainable building practices into projects. Generally, the earlier green building gets incorporated into the design process, the lower the cost.90

Another California study, performed in 2001, found that California developers estimated green buildings to cost ten to fifteen percent more than conventional buildings.91 Moreover, the October, 2002 issue of Consulting-Specifying Engineer stated that “the perception that green design is more expensive is pervasive among developers and will take time to overcome.” It also noted “inhibiting green design is the perception that ‘green’ costs more and does not have an economically attractive payback.” Further, “[d]evelopers typically presume a ten to fifteen percent cost premium for building green,” but “[a]ccording to those who actually build LEED certified buildings... this figure

89 A major problem with the LEED rating system is that “[v]irtually no data has been collected on conventional buildings to determine what the building would cost as a green building. And, surprisingly, most green buildings do not have data on what the building would have cost as a conventional building.” KATS, supra note 35, at 2.
90 Id.
91 KATS, supra note 35, at 12; see also Adam Berman, Green Buildings: Sustainable Profits from Sustainable Development (2001) (unpublished report, Tilden Consulting, on file with author at adam@isabellafreedman.org).
93 KATS, supra note 35, at 12; see also Siddens, supra note 92, at 30-34.
is substantially lower. In essence, the more experience a developer has using the LEED system, the lower his or her initial construction costs will be.

The question for the developer then becomes whether higher initial investment costs become justified through substantial future savings. Building Design & Construction’s November, 2003, White Paper on Sustainability, concluded that:

There may in some cases be a slight premium for taking a conventional design to the equivalent of LEED certified, but not always. A well-executed design that reduces infrastructure and building volume can produce a sustainable building at a premium of 1-2% at most. Going up in class to the equivalent of [a] Silver or Gold [Star] may push up the premium, but at considerable additional savings over the life of the building.

For example, in 2000, Seattle, Washington became the first municipality in the United States to adopt LEED as the standard for public construction. An analysis of Seattle’s 11 LEED-certified public buildings found that LEED certification does not add to the cost of a project, provided that certain measures are taken before breaking ground.

The payback periods for initial green construction costs may also not be as long as many developers think. Houston-based architect Kirksey, an active proponent of the green building movement, made the business case for a client’s 22,000 square foot green office building it designed in early 2002 by creating a “payback table” which illustrated the premium cost for each of the project’s green elements along with the corresponding time periods required for the developer to pay it back. One of the most expensive elements, insulated glazing on the building’s exterior curtain wall, required a payback period of only

97 White Paper, supra note 32, at 33.
99 Among these measures are including LEED requirements as part of the construction documents, building construction, and building commissioning requirements, selecting a design team that has sustainable design “embedded within the firm’s design culture,” including contractors, property managers, real estate analysts, budget analysis, crew chiefs, and custodians as part of the project team, selecting green design strategies that are “whole system in nature, and pursuing integrated design solutions that cannot be peeled off from the base project as “add alternates.” Id.
100 Contractor Sets an Example with Green HQ, BUILDING DESIGN & CONSTRUCTION, Nov. 2003, at 45 [hereinafter Green HQ]. The payback table includes periods varying from 3.2 to 11.2 years. Id.
5.9 years at a premium cost of $22,950.\textsuperscript{101} The client, Spawglass Construction Corp., agreed to the green elements because “the building would give [it] a marketing advantage by demonstrating its commitment to sustainable design.”\textsuperscript{102} The relatively small periods over which the premiums were to be paid back made its decision to go green a process that “was not lengthy.”\textsuperscript{103}

Prior to the seminal \textit{Costs and Financial Benefits of Green Buildings} study, several other less comprehensive studies were performed. These studies attempted to empirically analyze the actual costs and financial benefits of green buildings. In October of 2002, the David and Lucile Packard Foundation\textsuperscript{104} released a \textit{Sustainability Matrix and Sustainability Report} designed to analyze environmental goals for a 90,000 square foot office building.\textsuperscript{105} It found that with each increasing level of LEED rated sustainability, short-term costs increased, but long-term costs decreased substantially.\textsuperscript{106} An earlier study, performed by Xenergy for the city of Portland, Oregon, found a fifteen percent lifecycle savings upon bringing three standard buildings up to LEED certification standards.\textsuperscript{107}

With respect to high-rise construction, a 2002 EPA report found Energy Star-labeled office buildings to generate utility bills forty percent less than the average office building.\textsuperscript{108} Some critics have argued that high-rises can never be considered green because their construction alone consumes too much energy.

William Browning, a senior associate at the Rocky Mountain Institute who collaborated with Fox & Fowle at Four Times Square, has addressed these concerns:

Tall buildings... contain dense concentrations of material, and a large amount of energy is used to make those materials. However, over the life of a building, the embodied energy—the amount of energy it takes to make

\textsuperscript{101} Id.
\textsuperscript{102} Id. (statement of John English, Spawglass Senior Vice President).
\textsuperscript{103} Id.
\textsuperscript{105} See KATS, supra note 35, at 3, n.24. This comprehensive study evaluates the life cycle cost of six increasingly green designs, each built to a different standard of sustainability. Increases in initial capital costs are weighed against decreases in operating costs to determine net present value (NPV) for each building type over a 30, 60 and 100 year period. The study concludes that life cycle cost for a green building is considerably lower than for a conventional one. Id.
\textsuperscript{106} Id.
\textsuperscript{107} Id. at vii.
\textsuperscript{108} See BUSINESS CASE, supra note 76, at 3 (“For international developer and investor Hines, efficiencies gained from its Energy Star buildings are generating $13 million in annual savings based on 2000 evaluation.”).
the materials and construct the building—is a small fraction of the energy consumed in operations. In a suburban setting, the individual cars commuting to and from a building can cause a significant amount of energy as well. A tall, energy-efficient building in an urban setting where most workers use mass transit may be less energy-intensive than a low, large-floor-plate building in a suburban setting.\textsuperscript{109} Moreover, both commercial and residential buildings maintain high values by sustaining high occupancy rates, and green building systems provide for easier building maintenance; this makes such buildings easier to sell to tenants, and also command higher rental or sales values for owners.\textsuperscript{110}

Residential buildings, however, present developers seeking LEED certification with greater challenges than do commercial buildings because they demand higher energy and water use. The Solaire, a twenty-seven story structure ironically located just a few short blocks from Ground Zero in lower Manhattan’s Battery Park City, is America’s first green residential high-rise.\textsuperscript{111} High resource demands in residential buildings caused developer Albanese Corp. to estimate that the structure will cost 13\% more than a traditional residential high-rise building.\textsuperscript{112}

USGBC must address the initial cost discrepancies between commercial, residential, and public buildings in subsequent versions of LEED. It must “change the content and rigor [of LEED]... so as to address the need for ‘raising the bar’ in response to improvements in technologies, knowledge, data, and market advancement.”\textsuperscript{113} If incorporated into future versions of LEED, the empirical data presented by the types of studies presented above, as well as documented testimonials from the developers of America’s newest green buildings, could go a long way towards dispelling green movement fictions. The studies presented in this section are but a small fraction of the growing body of empirical data that suggests the truth: green buildings make financial sense and are worthy of every developer’s attention.

\textsuperscript{109} GISSEN, supra note 7, at 180.

\textsuperscript{110} See BUSINESS CASE, supra note 76, at 7 (“Features designed to cut energy and water bills help attract tenants to the property and increase the likelihood of continued occupancy.”).

\textsuperscript{111} Fairley, supra note 83 (“[Y]ou get more redundancy and resiliency n case of disruption, power outage or a terrible attack like 9/11.”) (discussing benefits of energy and water efficient building systems).

\textsuperscript{112} Berman, supra note 91, at 6. Interestingly, however, Albanese “admits that the project’s photovoltaic panels and black-water treatment system, two very expensive green technologies, account for the majority of the premium. Without these items, the cost to green would be just under 1\% of the total cost . . . .” Id.

B. Beyond the Bottom Line

While USGBC, other local green building programs, and the bulk of think tank research projects have largely emphasized the financial benefits of green design, its benefits are not strictly found at the bottom of a developer’s balance sheet. According to William S. Becker, the former director of the Center of Excellence for Sustainable Development at the United States Department of Energy, “[i]n the not too distant future, all development will be green. Developers, builders, and buyers will discover that green not only enhances their pocketbooks, but also their health and the quality of their lives. The developers who grasp this first will have an edge in a massive, emerging market.” For instance, numerous studies of sustainable design have concluded that a structure’s interior thermal environment, which includes temperature, humidity levels, and ventilation control, influences worker productivity and performance, the building’s overall air quality, and acoustics. Studies have also shown that personal control over environmental conditions such as temperature and ventilation leads to better work performance. In addition, connecting employees with the natural environment by providing views and importing outdoor amenities such as fountains and trees reduces worker stress and improves overall psychological and emotional functioning.

Not all developers, however, are convinced. Some have stated they would like to see more empirical research on whether green buildings do in fact improve the productivity of occupant workers before drawing any conclusions about the viability of this particular arm of the green building movement. USGBC must more proactively procure data about these benefits and alert the industry to them by including them in later versions of LEED.

C. Conclusions about the Benefits of Green Design

Building Design & Construction’s White Paper performed a September, 2003 survey of the 76,001 architects, contractors, engineers, and owners who receive the magazine. The survey asked what readers thought of green design, as well as how invested their firms were in pursuing sustainable design and construction techniques. 44% responded that green design added significantly to first costs,
42% said that the real estate market was neither interested nor willing to pay a premium for green elements, 35% felt green design was hard to justify even in light of studies which revealed the movement’s potential for long-term savings, 19% were simply uncomfortable with new green ideas and technologies, 16% thought LEED was too complicated and requires too much paperwork, and 24% had no comment.121

The real estate industry continues to be conflicted over the benefits of green design. To date, the benefits emphasized by USGBC have been entirely financial and little reference has been made to either worker productivity or architectural choices that destroy both immediate and distant natural environments. Green building programs must change their emphasis, or at least put other benefits on the same solid empirical footing as bottom line economics, before developers at large will see the movement as having the mass appeal it deserves.

IV. LEED: A SUFFICIENT STANDARD FOR SUSTAINABLE 21ST CENTURY HIGH-RISE ARCHITECTURE?

Four Times Square’s unique status as America’s greenest high-rise building, despite pre-dating LEED or any other state or local green building program, positions a case study analyzing its green features to help advance numerous arguments in support of the long-term viability of green design in American high-rise buildings. Part IV of this article examines Four Times Square’s green elements through the prism of the most recent version of the LEED Green Building Rating System to show that, while LEED can be a beneficial incentive to developers of high-rise properties, it remains far from perfect. This is largely true because LEED fails to link its various provisions to the numerous other green building programs in existence at the state and local levels, which provide various financial incentives to participating developers.122 Moreover, the LEED guidelines, particularly with regard to their most financially beneficial and environment-friendly categories, are not detailed enough for a project team’s unsophisticated contractors. It is telling that no skyscraper built in the United States since Four Times Square has sought LEED certification, though it should be noted that several developers in New York City have recently announced that they intend to do so.123

feelings of many who completed the survey: 'Green building is the right direction for construction but also should be used with common sense. Spending millions extra with insufficient payback will only hurt the green building movement.’” Id. at 17.

121 Id. at 14-17.

122 See WHITE PAPER, supra note 32, at 22-23, for a comprehensive list of incentives provided at the state and local levels.

123 The new Hearst Corporation headquarters building at Eighth Avenue and 56th Street in
A. Four Times Square: America’s First Green Skyscraper

Although it still reigns supreme as the United States’ only green high-rise building, Four Times Square was completed prior to even the pilot phase of LEED 1.0.124 Durst and the rest of its project team chose to go green because each member had a long history of environmental awareness:125 “it was the synergy and common interest of the three firms [contractor, architect, and developer] that really made Four Times Square work.”126 Most large scale construction project teams, however, do not work with such a level of familiarity with the green building effort.127 LEED attempts to bridge the gap between such green-novice project teams and the high learning curve, which has damaged the movement’s perception among developers.128

The construction guidelines at Four Times Square announced that the building was to offer tenants “an office tower bristling with the latest technologies that will be demanded by sophisticated tenants as they enter the 21\textsuperscript{st} Century.”129 Prospective tenants were encouraged to tie into the building’s pre-existing green infrastructure when fitting out their respective floor space by taking advantage of Four Times Square’s “high-performance windows and higher than normal ceilings,” keeping “sections of the perimeter free of private offices to let more natural light penetrate the interior of the space,” and “consolidating rooms with similar uses and schedules.”130 Durst’s primary goal in erecting the structure, though, was “to set a new standard in environmentally responsible

124 See discussion supra Part II.B, for a description of LEED’s historical development.
125 See Gissen, supra note 7, at 179, for a detailed description of the environmental backgrounds of the project team.
126 Id. (statement of Bruce S. Fowle, principal of Four Times Square architect Fox & Fowle).
127 See White Paper, supra note 32, at 2-5.
128 See generally LEED 2.1, supra note 19.
130 Id. The bulk of the guidelines that Durst used in creating its comprehensive green design for Four Times Square emphasized the use of energy efficient, gas-fired heating, ventilation, and air conditioning (“HVAC”) systems; fresh air circulation at four times the then-current code requirements; high-performance windows that let in light while at the same time retaining the inside air temperature; extra-large windows designed to maximize permitted daylight, thus lowering the overall need for electric lighting; digital monitoring systems for HVAC; extra levels of insulation to minimize the use of HVAC; variable speed drives on fans and pumps for improved energy efficiency; recycled and recyclable materials used during the various construction phases; and recycling chutes on each floor that tenants were asked to plug into. Id.
construction.' To that end, the subsequent creation of LEED seems to indicate that the developer was successful.

B. LEED Credit Category 1 Analysis: Sustainable Sites ("SS")

LEED’s first credit category gives developers up to fourteen possible points for wisely choosing building locations. Credits are earned for selecting sites that “do not include sensitive site elements and restrictive land types.” This channels development towards urban areas with existing infrastructure, rehabilitates damaged sites such as brownfields, provides access to public transportation, accommodates alternative means of transportation, and conserves natural areas by sharing building facilities such as parking decks. LEED’s building location credit system thus encourages development with as small a footprint as possible to minimize site disruption.

The difference between low-rise building footprints and their high-rise counterparts illustrates the importance of high-rise buildings to the green building movement. If a space comparable to Four Times Square’s 1.6 million square feet of office space were to be divided up into individual buildings in a less dense suburban or rural location, it would require a site of 140 acres, excluding the additional space necessary for utilities and access infrastructure. Standing forty-eight stories tall, Four Times Square sits upon only one acre of land in Manhattan’s Time Square, adjacent to nine of New York City’s twenty-three subway lines, and just a few short blocks away from the regional transportation hubs of Grand Central and Penn Stations. Minimizing a building’s footprint by building a skyscraper thus has the potential to drastically reduce its impact on the natural environment.

The guidelines provided by USGBC for SS, however, are decidedly

---

131 Id. Durst is a “committed environmentalist” who is part-owner of the largest organic farm in the state of New York. See Real Estate Roundtable, supra note 2. This might explain his enthusiasm for fronting substantial, above-average costs for his building to incorporate holistic green design. Id.
132 LEED 2.1, supra note 19, at 2.
133 Id.
134 A brownfield is an abandoned or underused location that is typically the site of a former industrial complex, gas station, oil storage facility, or other building that required chemicals which may have polluted the soil or water table. The regeneration of a brownfield is a sustainable activity because it involves the cleanup of a polluted site and subsequent efficient use of the formerly unusable land. GISSEN, supra note 7, at 183.
135 See generally LEED 2.1, supra note 19, at 1-15.
136 See GISSEN, supra note 7, at 180 ("The incredible concentration on a small piece of land, which 95 percent of the workers—of whom there are 6,000—get to work by public transportation in itself makes it sustainable.") (statement of Bruce Fowle, principal of Fox & Fowle).
137 See Durst Website, supra note 129.
138 Kibert, Listen to Your Mother, supra note 12, at 38.
By nature, the category encourages high-rise construction, but it provides little real incentive or guidance for developers who choose to build in urban locations where almost all buildings are high-rises with small footprints and are easily accessible to mass transit. LEED should consider offering financial incentives to developers similar to those provided by the city of Austin, Texas, which helps developers offset the higher costs of building in urban areas through the use of its Smart Growth Matrix credits. LEED should also make reference to how much land area a skyscraper saves and link itself to tax credits for developers purchasing plots for high-rise development.

C. LEED Credit Category 2 Analysis: Water Efficiency (WE)

WE is the smallest of the LEED 2.1 credit categories, awarding developers up to five credits for taking measures to improve water efficiency. Durst did not provide standards for water efficiency at Four Times Square; LEED nevertheless awards points to developers who limit or eliminate the use of potable water for landscape irrigation, incorporate innovative wastewater technology into the building’s sewer systems, or achieve a substantial reduction in the overall amount of water that the building consumes.

WE illustrates one of the most pervasive problems with the LEED rating system. Some LEED credits, or performance requirements, can be met with ease; others are more complicated and, from the outset, require a project team to think in a much more integrative fashion than merely ordering more efficient building materials off of a checklist. Guidance from USGBC in this category is generally superficial. Using low-flow faucets or waterless urinals, for example, is a simple way to achieve LEED points. But some LEED points can be met quite simply, while with others “it’s a lot more complex and [the project team] has to be thinking in a lot more integrative fashion.”

---

139 See LEED 2.1, supra note 19, at 1-15. The Potential Technologies and Strategies for the Development Density credit, for example, are “[d]uring the site selection process, give preference to urban sites.” Id. at 3.

140 Smart growth is “characterized by mixed-use, compact, walkable communities, built onto existing towns and cities, where open space is protected.” Timothy Beatley & Richard C. Collins, Americanizing Sustainability: Place-Based Approaches to the Global Challenge, 27 WM. & MARY ENVTL. L. & POL’Y REV. 193, 198 (2002); see also Smart Growth Online, at http://www.smartgrowth.org (last visited Mar. 18, 2004); see also WHITE PAPER, supra note 32, at 22; see also City of Austin Green Building Program, at http://www.ci.austin.tx.us/greenbuilder (noting that Austin offers waivers of development fees and public investment in new or improved infrastructure) (last visited Nov. 1 2004).

141 See Fairley, supra note 83, for a description of the state of New York’s green building tax credit program.

142 Potable (drinking) water is generally not used in landscape irrigation techniques. See generally LEED 2.1, supra note 19.

143 Id. at 16-20.

144 See WHITE PAPER, supra note 32, at 29-30 (“[S]ome LEED points . . . can be met quite simply, while with others ‘it’s a lot more complex and [the project team] ha[s] to be thinking in a lot more integrative fashion.’”).
example, can satisfy the LEED requirements at little to no additional cost, but no mention of this is made in the guidelines. Further, the Potential Technologies and Strategies section, accompanying the description of each WE credit, merely suggests that "high-efficiency fixtures and dry fixtures such as composting toilets and waterless urinals" be provided to reduce wastewater amounts, and no explicit instructions are given as to how a 30% reduction in overall water use is to be achieved.

There are many ways in which WE can be improved. The relative ease with which the requirements of this category can be met should be clearly pronounced in the guidelines. For high-rise buildings, the impact on water consumption that urinals and faucets have is substantial; hard facts in writing would provide the unsophisticated developer with reasons to choose low- or no-flow water systems, which generally cost the same amount as other higher water consumption appliances. Local programs also exist which give developers cash rebates for installing systems that conserve water. LEED must provide similar incentives to make the WE guidelines more credible and of greater practical significance to the developer.

D. LEED Credit Category 3 Analysis: Energy & Atmosphere (EA)

The solid body of empirical data slowly emerging about the financial benefits of green buildings rests largely upon the shoulders of EA. The largest of LEED's five credit categories, EA lists three prerequisites to earning any of the seventeen points available under its various sub-headings. The largest of those sub-headings, "optimizing energy performance," gives a project team up to ten points for reducing design energy costs compared to the energy cost

---

145 Id. at 30. However, "earning a point for reducing the use of potable water for irrigation by 50% (WE 1.1) cannot be met simply by installing sophisticated controls . . . ." Id.
146 LEED 2.1, supra note 19, at 18.
147 Id.
148 Id. at 20.
149 WHITE PAPER, supra note 32, at 29-30.
151 See generally KATS, supra note 35; see also WHITE PAPER, supra note 32, at 40 ("[T]he data on the bottom-line benefits of sustainable design, such as dollar savings from reduced energy . . . consumption, is much more reliable than that related to many of the less-tangible economic, social, health and well-being benefits of green buildings . . . .").
152 See LEED 2.1, supra note 19, at v. Building elements and systems must be designed and calibrated to insure that they operate as contemplated, a minimum level of energy efficiency for the base building systems must be established, and zero CFC-based refrigerants may be used in new or retrofitted base building HVAC&R systems. Id. at 21-23.
budget for energy systems regulated by ASHRAE/IESNA\textsuperscript{153} Standard 90.1-1999.\textsuperscript{154} The LEED guidelines distinguish between regulated and non-regulated energy systems, and introduce two methods for architects to separate the energy consumption of regulated systems.\textsuperscript{155} They also encourage project teams to apply for innovation credits if the energy consumption of any non-regulated system is also reduced.\textsuperscript{156}

Efficient lighting systems have tremendous potential for conserving energy, thereby saving high-rise owners substantial amounts of money.\textsuperscript{157} As environmentally conscious as the Four Times Square project team was, its decision to go green would not have been made unless Durst, a highly sophisticated developer, knew with some certainty that its initial investment would be returned to it at some point in the future.\textsuperscript{158} Durst required a level of 1.0 watt per square foot average connected load, including task lighting,\textsuperscript{159} and the project team accomplished this goal by incorporating a variety of energy-efficient lighting systems.\textsuperscript{160}

Heating and cooling a high-rise building typically takes a toll on the environment. To reduce the impact, Four Times Square has natural gas-powered absorption chillers and heaters installed on the roof to circulate chilled and heated water to cool and heat the building. Most chillers and heaters that supply heating, ventilation, and air conditioning (HVAC) to buildings of comparable size use ozone-depleting chlorofluorocarbons (CFCs);\textsuperscript{161} those at

\textsuperscript{153} LEED 2.1, \textit{ supra} note 19, at 24. ASHRAE/IESNA Standard 90.1-1999, Energy Standard for Buildings Except Low-Rise Residential Buildings, has been established by the DOE as the commercial building reference standard for state building energy codes under the federal Energy Conservation and Production Act. The Act requires all states to certify that they have state energy codes in place that are at least as stringent as 90.1-1999, or justify why they cannot comply with this. \textsuperscript{160} Engineers "incorporated energy-efficient lighting, including high performance fixtures with central controls in public spaces, exit signs that use light emitting diodes (LED), and occupancy sensors in unoccupied areas, including stairwells. Window glazing was designed to provide excellent daylight to areas near the building’s perimeter. The low e-glass curtain wall allows light in, keeps solar heat and ultraviolet rays out, and decreases heat loss in the winter." \textsc{Four Times Square, Highlighting High Performance, available at} http://www.rebuild.org/attachments/SolutionCenter/HPB4TimesSquare.pdf (last visited Nov. 1, 2004); see also Durst Website, \textit{ supra} note 129 [hereinafter \textsc{Highlighting High Performance}].

\textsuperscript{161} CFCs are composed of atoms of chlorine, fluorine, and carbon arranged in a stable chemical
Four Times Square were designed to use an absorber, a generator, a pump, and a recuperative heat exchanger, which eliminated the need for CFCs.

To further decrease energy usage, Four Times Square incorporated an innovative, state-of-the-art, thin-film photovoltaic (PV) panel system to replace mirror glass spandrels\(^{162}\) from the 37\(^{th}\) to the 43\(^{rd}\) floors on the south and east faces of the building. A relatively small area for PV, the system still produces enough output to power five to seven houses.\(^{163}\) PV systems are generally referred to as solar cells and “are semiconductor devices that convert sunlight into direct current (DC) electricity.”\(^{164}\) Groups of these cells are “electrically configured into modules and arrays, which can be used to charge batteries, operate motors, and to power any number of electrical loads. With the appropriate power conversion equipment, PV systems can produce alternating current (AC) compatible with conventional appliances and operate in parallel with, and interconnected to, the utility grid.”\(^{165}\) PV systems were developed in the mid-1950s and are cost-effective in situations where it may be difficult to run conventional power lines, such as in extremely dense urban locations.\(^{166}\)

PV at Four Times Square was the first major commercial application of such a building-integrated system in the United States, and its successful use at Four Times Square established that it is a viable option for high-rise construction projects.\(^{167}\) The system demonstrates that the “large-scale production of clean, silent solar electricity is possible at the point[s] where it is needed most: at the point of greatest use.”\(^{168}\) Moreover, the system was integrated into the building’s curtain wall and thus fit in with the rest of the building’s aesthetic, structural, and electrical standards.\(^{169}\) In fact, the success of PV at Four Times Square led Durst to announce in early 2004 that it would also seek to use wind power to...

generate electricity for the building.\textsuperscript{170}

EA category credits provide an exciting glimpse at just how effective LEED can be in the future. Because of the generally reliable body of data about the financial benefits for developers using these types of energy-efficient systems, it is imperative that USGBC create more incentives for project teams to incorporate them in large-scale construction. Moreover, Four Times Square proves that such systems are viable options for Class A real estate projects. Local programs have found ways to provide both commercial and residential developers with cash rebates for qualified energy systems; LEED must do the same by aligning itself with government subsidies to qualified projects and developers.\textsuperscript{171} PV’s success at Four Times Square, in particular, shows that holistic, building-integrated systems are possible in high-rise construction. Future versions of LEED must refer to these successes, thereby encouraging their further use in high-rise construction.

\textit{E. LEED Credit Category 4 Analysis: Materials & Resources (MR)}

As a prerequisite to earning any of the category’s thirteen possible certification points, MR requires that an accessible area serving the entire building be provided to separate, collect, and store materials for recycling paper, corrugated cardboard, glass, plastics, and metals.\textsuperscript{172} Durst’s Four Times Square guidelines are similar to Credit MR 3.1, “Resource Reuse,” which is awarded where salvaged, refurbished, or reused materials, products, and furnishings compose at least five percent of building materials.\textsuperscript{173} Another credit can be earned if that figure increases to ten percent.\textsuperscript{174} In the same vein, credits MR 4.1 and 4.2 award points for the use of materials with recycled content that constitute five and ten percent of the total project materials, respectively.\textsuperscript{175} Credit MR 5.1 provides an additional point when twenty percent of building materials and products are manufactured within a radius of 500 miles of the project site.\textsuperscript{176}

\textsuperscript{170} See Lew Sichelman, \textit{This Home is Where the Green Is}, N.Y. NEWSDAY, Jan. 23, 2004, at C03.
\textsuperscript{171} See City of Austin Green Building Program, supra note 140; see also WHITE PAPER, supra note 32, at 22.
\textsuperscript{172} See LEED 2.1, supra note 19, at 33.
\textsuperscript{173} Id. at 39 (stating intent of Credit MR 3.1 is to “[r]euse building materials and products in order to reduce demand for virgin materials and to reduce waste, thereby reducing impacts associated with the extraction and processing of virgin resources”); see also Durst Website, supra note 129.
\textsuperscript{174} Id. at 39 (describing MR Credit 3.2).
\textsuperscript{175} Id. at 34-36.
\textsuperscript{176} Id. at 43. MR Credit 5.2 again provides an additional point if the percentage of regional materials used in the project reaches fifty. \textit{Id.} at 44. However, BUILDING DESIGN &
Credits MR 1.1-1.3, "Building Reuse," purport to "extend the life cycle of existing building stock, conserve resources... reduce waste[,] and reduce environmental impacts of new buildings as they relate to materials manufacturing and transport."\(^{177}\) Credits are earned for maintaining a minimum of either seventy-five percent or all one hundred percent of existing wall, floor, or roof systems of the structure that stands on the new building’s site.\(^{178}\) Strategies the USGBC suggests for receiving these points include reusing the structure, shell, and non-shell elements of the existing building, removing elements that pose contamination risk to building occupants, and upgrading outdated existing building components such as windows, mechanical, and plumbing systems.\(^{179}\)

Environmental criteria for building materials and construction methods at Four Times Square were included in the drawings and specifications sent out to individual subcontractors. The general contractor, Tishman Construction, administered the criteria and all tenants were encouraged to adopt the same environment-friendly construction standards for their interior fit-out construction.\(^{180}\) Durst also provided Tishman with a comprehensive set of guidelines for managing the over fifty subcontractors who worked on the building.\(^{181}\) These guidelines mandated that building materials could not be toxic or hazardous to the building’s construction workers or its future tenants, recommended the use of products containing a “high percentage of recycled content,” required a waste management plan for excess construction materials, recommended “modular, prefabricated, or pre-assembled systems to minimize construction waste,” and required all suppliers to be qualified “in terms of environmentally responsible manufacturing.”\(^{182}\)

The interior of the building was also designed to be resource sensitive. For instance, Fox & Fowle equipped each floor of the building with two recycling chutes (one for paper and one for “wet” trash) located in the building core.\(^{183}\) Each was connected to a corresponding container in the building’s loading dock area.\(^{184}\) Tenants were encouraged to set up their own recycling systems and

\(^{181}\) Id.  
\(^{182}\) Id.  
\(^{183}\) Id.  
\(^{184}\) Id.
programs on their floors to take advantage of the building system.\textsuperscript{185} Moreover, the building’s interior finishes were composed of materials with a relatively high proportion of recycled materials, and tenants were encouraged to build their spaces out with similar materials; such materials were to include carpeting, ceramic tile, and gypsum wall board.\textsuperscript{186}

Durst’s use of comprehensive materials and resources guidelines at Four Times Square illustrates LEED’s viability in this particular category. Because MR is one of the simplest and least integrative of the credit categories, USGBC’s guidelines are clear and easy to understand, even for an unsophisticated contractor or developer. However, USGBC ought to follow local programs, such as those in Berkeley and Los Angeles, which have created partnerships with city agencies and departments to provide further information about advanced materials and technologies that can be incorporated into a green building to save the developer substantial amounts of money.\textsuperscript{187} It would also be practical for LEED to include data about precisely how MR is an environment-friendly category.

\textbf{F. LEED Credit Category 5 Analysis: Indoor Environmental Quality (EQ)}

The goal of the EQ credit category is to “prevent the development of indoor air quality problems in buildings, thus contributing to the comfort and well-being of the occupants.”\textsuperscript{188} The category’s prerequisites require developers to prohibit tobacco smoking in the building unless in a specially designed smoking room and place any exterior designated smoking areas at a distance from entrances and windows.\textsuperscript{189} Up to fifteen credits are earned for a variety of preventive measures: installing carbon dioxide monitoring systems; incorporating ventilation systems in accordance with federal standards; maintaining an air quality program during the construction and pre-occupancy phases of the project to prevent any future air quality problems; reducing the quantity of indoor air contaminants from adhesives, sealants, paints, coatings, carpets, and wood composites; taking measures to prevent building occupants from exposure to hazardous chemicals affecting air quality; giving building occupants control over thermal and lighting systems; designing the building to maintain temperature and humidity comfort ranges; installing a permanent temperature and humidity monitoring system “supporting the productivity and well-being of building occupants;” and providing for a connection between

\end{footnotes}
indoor spaces and the outdoors "through the introduction of daylight and views into the regularly occupied areas of the building." Durst's guidelines maintained that improving indoor air quality "improves productivity and reduces absenteeism." Four Times Square's mechanical systems were designed to bring four times more fresh air into the building than the building code required at the time. Tenants were "encouraged to complement this high standard and use materials, finishes, and systems which maintain the quality of this fresh air." 

EQ, the final credit category in LEED 2.1, presents an interesting dichotomy. It provides by far the most substantial guidelines of all the Credit Categories by both making reference to existing federal standards and giving project teams concrete benchmarks with which to work. Future versions of LEED should revise the other categories to include similar references, and should also refer to state and local programs. One problem with EQ, however, is that little of the research about the benefits of improved indoor air quality has been performed on the most recent green buildings, many of which have been high-rises. Moreover, data on the financial benefits from reduced energy and water consumption systems, in the eyes of the real estate industry, is more reliable. USGBC must take steps to change that perception.

G. Conclusions about LEED: A Step in the Right Direction, But More is Necessary

As discussed in Part II, supra, the effect a building has on the natural environment through the use of natural construction materials is profound. That impact can be softened if the building is designed to incorporate less material. At Four Times Square, modern design elements were used in the "support structure of the building itself, specifically in the use of over-arching hat trusses at the top of the tower. These strengthen the building by tying together the vertical structural members and increasing the [overall] strength of the building, while at the same time reducing the tonnage of structural steel needed." Concrete was also used as a structural element to further reduce the amount of

196 See id.
steel required. In addition, the existing foundation footings at the corner of 42nd Street and Broadway were reused and over 65% of the construction debris was recycled. The lack of any credits for innovative engineering and architecture that substantially decreases the overall volume of material required to erect a high-rise is an obvious flaw in the LEED rating system. USGBC should include a credit category, which encourages architects to design buildings with less material as compared to a predetermined industry standard.

The largest obstacles to the development of uniform standards for green buildings are the incomplete integration of systems within projects, the lack of lifecycle costing, and insufficient technical information. The current LEED guidelines serve only to perpetuate those problems. By merely serving as a laundry list of green elements which do not refer to each other or provide substantial guidance as to how the proven empirical benefits are to be achieved, LEED falls short of being a desperately needed, twenty-first century sustainable standard.

There are, however, many simple ways LEED could be made more effective. Existing state and local programs, as presented in Part II.A., supra, should include the LEED guidelines as the standard for awarding incentives such as expedited permit reviews, tax credits, and preferred loans. This would further establish LEED as the American standard for green design. Future versions of LEED should be redrawn to incorporate broader policy justifications for green design, discussed infra in Part V. Finally, USGBC should follow the White Paper Action Plan presented by the editors of Building Design & Construction in the conclusion of their November, 2003 White Paper on Sustainability.

V. THE SOLUTION: BETTER AND BROADER ARGUMENTS FOR GREEN BUILDING

The creation of LEED and USGBC was a critical step in the right direction.

198 Id.

199 This article joins BUILDING DESIGN & CONSTRUCTION's WHITE PAPER in calling upon the real estate industry to devote more resources towards developing a larger body of empirical data across a wider range of green building.

200 Integrated building systems are created through a design process where green elements of the building are not "add-ons to the rest of the project" but are instead "integrat[ed] . . . into the base budget. Establishing an integrated design can lead to capital savings: investing 3% of total project costs during design can yield at least 10% savings in construction through design simplifications and fewer change orders . . . ." WHITE PAPER, supra note 32, at 32.

201 See id. at 9-10, for a description of the "substantive and complex issues that are [currently] being addressed by the LEED committee and USGBC staff."

202 See id. at 23-24, for a list of cities and states which have adopted LEED-based regulations for both public and private projects.

203 See id. at 40-44. The White Paper Action Plan "strive[s] to present recommendations that would be seen as both practical and economically feasible." Id.
towards ensuring a sustainable future for America, but much more must be done
to eliminate the catastrophic effects buildings have upon the natural
environment. The impetus for encouraging developers to incorporate green
features into their buildings through the LEED rating system and USGBC
documentation rests decidedly on economic incentives. Congress must
propose more programs and incentives for developers to incorporate green
design elements into their structures. It should also rethink how to design
policies that encourage green building developments. The policies must provide
more empirical evidence establishing green building benefits relating to
occupant health, performance, and well-being. Part V of this Article serves to
demonstrate that, while a solid body of empirical evidence does exist about such
benefits, more comprehensive studies must be performed about the latest crop of
green buildings before any data is built into next-generation LEED rating
systems.

A. Lessons from September 11th and the World Trade Center: Why the Modern
Skyscraper Must Be Rethought

The sensitivity to high-rise building construction in the aftermath of
September 11th and the destruction of New York City’s World Trade Center
cannot be ignored. Numerous calls have been made in both popular and
academic circles for a halt to skyscraper construction, particularly in light of the
sharp downturn in the American economy and corporate decisions to house
workers in disparate locations. Moreover, the public’s general distaste for
sterile, suburban corporate office centers and isolated subdivision housing
complexes, and its continued fascination with urban places has manifested itself
in the New Urbanism movement. The public’s desire to return to the urban
fabric demands sustainable standards for construction in line with our twenty-
first century perspective on our role in the global ecosystem. Those
sentiments are entirely at odds with the reality of how modern American
business is increasingly conducted: through the home-office media center, which
ostensibly allows workers to never leave their homes as they perform

---

204 See discussion supra Part II, for a detailed discussion of those effects.
205 See discussion supra Part III, for further examination of those incentives.

increasingly technology-oriented jobs.\footnote{See GISSEN, supra note 7, at 78.}

America’s suburbs, where the bulk of the United States’ 296 million citizens reside, grew increasingly more sterile and isolated through the end of the 20th century.\footnote{Id.} A lack of street trees, no sidewalks, and large home-to-lot ratios leaving little room for landscaping became commonplace.\footnote{Id.} Garages attached to homes soon became ubiquitous elements of subdivision life, and it was soon possible for residents to go from house, to garage, to car, to work without setting foot outside, in the natural environment.\footnote{Id.} This trend supports the theory that by spending so much time in artificial environments, people become detached from the larger natural ecosystem of which they are an integral part.\footnote{Id.} Accordingly, they no longer view themselves as essential to the Earth’s long-term ecological future.\footnote{Id.}

In response to global indifference to the environment, the World Conservation Strategy has for over a decade called upon people to take responsibility for their impacts on nature by conserving ecological processes through frugal, efficient, and sustainable resource use.\footnote{DAVID A. MUNRO, CARING FOR THE EARTH: A STRATEGY FOR SUSTAINABLE LIVING 14 (1991).} “The ability of a country to follow sustainable development paths is determined to a large extent by the capacity of its people and institutions, as well as by its ecological and geographical conditions. Specifically, capacity-building encompasses the country’s human, scientific, technological, organizational, institutional, and resource capabilities.”\footnote{Agenda 21: Programme of Action for Sustainable Development, U.N. Sustainable Environments.} People

Computers now provide the convenience of reliable communication with corporate headquarters anywhere in the world and the luxurious advantage, for information-based employees, of living in sylvan surroundings, with only occasional trips to the city for office conferences . . . . As commuter traffic becomes increasingly unbearable, the statistical consequence of more than ten thousand American business executives converting to this digitally-connected suburban lifestyle each year seems destined to negatively affect the future of high-rise construction. \footnote{This article proposes that this is the best, though as of yet least advanced, argument in support of the green building movement. By harmonizing New Urbanism and green building principles, USGBC would position LEED to apply universally across modern American society.} And, of course, the development industry is now faced with the disconcerting reality that terrorists view such structures as symbolic targets, which is certain to adversely affect developers’ desire for trophy buildings.

\footnote{See JANE SILBERSTEIN & CHRIS MASER, LAND USE PLANNING FOR SUSTAINABLE DEVELOPMENT at introduction (2000), for a vivid description of the common suburban neighborhood.}
will choose sustainable living when they are persuaded that it is necessary to do so, when they have sufficient incentives for doing so, and when they are empowered with the required knowledge and skill.\textsuperscript{219} Therein lies a much stronger foundation for the green design movement, and the grounds upon which Congress, state, and local governments must be petitioned to increase awareness of USGBC, LEED, and other green design programs.

Currently, LEED's SS category is in the best position to address these concerns. The category should be rethought in light of September 11\textsuperscript{th} and the increasing threat of terrorism within the borders of the United States. People who commute to work in post-9/11 America are naturally more apprehensive about being apart from their families, and given the opportunity, would choose to live in greener communities which allow them a shorter commute.\textsuperscript{220} By stressing those sentiments to developers, particularly by emphasizing the benefits of higher occupancy rates and, in turn, higher property valuations those rates earn, future revised SS categories would carry increased practical significance and be better able to advance the current goals for the category as professed by USGBC.\textsuperscript{221}

\textbf{B. The Human and Social Benefits of Green Building}

The green building movement, in general, can be attributed to the "sick building syndrome" scare of the 1960s and 70s.\textsuperscript{222} The syndrome describes various health- and discomfort-related symptoms that a building's occupants experience from exposure to indoor air pollutants.\textsuperscript{223} The green building movement helped to ameliorate some of the problems at the root of the syndrome, both physical and psychological.\textsuperscript{224} A 1993 study performed at the Rensselaer Polytechnic Institute attempted to assess the impact of giving

\end{itemize}
\end{footnotesize}
workers personal control over environmental conditions at their workstations.\textsuperscript{225} It found that productivity, measured by actual work output, increased when weighed against worker performance in an otherwise standard office space.\textsuperscript{226} Two other studies, which observed over 11,000 workers in 107 different European buildings, found that giving workers personal control over temperature and ventilation conditions resulted in increased productivity, fewer illness symptoms, and less truancy.\textsuperscript{227} A 1999 study, "Skylighting and Retail Sales, An Investigation Into the Relationship Between Daylighting and Human Performance," found with 99% statistical certainty that stores without skylights stood to realize a 40% gain in total sales upon their addition.\textsuperscript{228} Marketing benefits of going green are similarly important. Green projects generally receive higher than average media attention, giving buildings and those who develop them greater exposure and increased access to potential tenants.\textsuperscript{229}

The majority of the studies performed to analyze the human benefits of green buildings were performed prior to the 2000 enactment of LEED.\textsuperscript{230} USGBC must remedy this by sponsoring comprehensive studies across all areas of the industry. Building Design & Construction's White Paper, for example, suggests that the national academies\textsuperscript{231} undertake comprehensive studies of these less tangible benefits of green design across the public, commercial, and residential sectors of the construction industry and provide test cases from the latest green

\end{footnotesize}
buildings. The results of the existing, less-than-comprehensive studies are highly encouraging, and should give USGBC further reason to pursue more modern studies to incorporate as empirical data in future versions LEED. This body of data should be included as part of an incentive credit category, where developers are invited to achieve levels similar to these potential USGBC case studies.

CONCLUSION

The USGBC and its LEED rating system are two steps in the right direction towards reducing the effects modern high-rise buildings have on the natural environment. However, stronger arguments exist for justifying the inclusion of more green elements in modern construction projects than are included in LEED. Currently, there are no real financial incentives compelling owners to attempt LEED certification. LEED itself remains more of a checklist than a comprehensive set of green building guidelines. Next-generation LEED systems must help developers create far more integrated green building systems. Green design comports with the New Urbanism movement, encourages people to use alternate means of transportation, and most importantly, helps to leave the natural environment intact. More research must be done, however, to empirically determine the financial savings green design provides for large construction projects. It is imperative that USGBC link LEED with the numerous state and local green building programs already in existence. Further, the next generation LEED rating systems must become the standard by which incentive programs evaluate green buildings. Finally, more financial incentives and information must be provided to owners to dispel the various fictions that permeate the real estate industry about the green building movement.

The connection between the environment and a building’s occupants seems tenuous at first but is in fact quite profound. Increasing green features in the workplace, residential buildings, and residential sub-development will translate into more environmentally sensitive and active Americans. Research must be performed to determine the viability of this potentially sweeping argument. As

---

232 Id.

233 See Heerwagen, supra note 49 (“[M]any people believe sustainable building design will become a more common practice once the human benefits are identified, primarily the productivity gains associated with the provision of high quality interior environments. The argument behind this belief is that [s]ince salaries of building occupants exceed by far the construction or operation costs of a building, any sustainable design features that positively impact productivity, however modestly, will pay back the investment over time.”). But see WHITE PAPER, supra note 32, at 35 (“[T]he larger concern is that the real estate community is not convinced by these studies. While a growing number of developers and owners may be getting more comfortable with the energy and water savings of green buildings, they still have trouble pinning down the dollar value of the human and social benefits of sustainable development.”).
Churchill said, we do indeed have the power to shape our buildings. We also have the power to make sure they shape us into a more environmentally aware people, in tune with the desperate need for a sustainable future for our planet.
